(54) **DEVICE FOR IRRADIATING LASER BEAMS.**

(57) This invention relates to a device for irradiating laser beams such as a laser beam irradiating body used to apply laser beams to an animal, human, for example, tissue to perform incision, transpiration, or thermotherapy on the tissue, and, in particular, to an irradiating device exceedingly effective for thermotherapy on cancer, in which a laser-permeable body is brought into contact with the surface of an animal tissue directly or through a surface layer that will be described later. The device is provided with a laser-permeable body and other bodies for transmitting laser beams, for example, glass fibers to project laser beams onto this permeable body, in which said permeable body contains scattering powder to scatter laser beams and is made of laser-permeable plastic material.

BEST AVAILABLE COPY

TECHNICAL FIELD

This invention relates to laser light irradiation apparatus such as an laser light emitter, which irradiates laser light to living tissues of an animal such as a human body to permit an incision, vaporization of the living tissues or a thermal therapy and, more particularly, to laser light irradiation apparatus by which a thermal therapy can be carried out efficiently for cancer tissues and the like while the penetrating member of laser light irradiation apparatus is brought into contact with the surface of the living tissues directly or through the intermediary of a surface layer provided on the penetrating member.

Prior Art

Medical treatments such as incisions of living tissues of animal organisms by laser light irradiation are conspicuous due to its ability of hemostasis in these days.

It had been the conventional method that the laser light was irradiated from the fore end of an optical fiber which is brought out of contact with the living tissues. But this method causes severe damage to members of the optical fiber. Therefore, a method which has been utilized lately is as follows;

First, laser light is transmitted into an optical fiber, whose fore end portion locates adjacent to treated living tissues. Next, the laser light is fed into an emitting probe from the optical fiber. This emitting probe is brought into or out of contact with the living tissues. Then, the laser light is emitted from the surface of the probe for irradiating against the living tissues. (hereafter "living tissue" is sometimes expressed by "tissue" only).

The inventor developed many kinds of contact probes which are utilized for various purposes.

Further, lately, localized thermal therapy is drawing special attention as a carcinostatic therapy. According to this method, cancer tissues are destroyed by keeping the cancer tissues at a temperature of about 42-44°C for 10-25 minutes by the laser light irradiation. The effectiveness of this method has been reported by the inventors in the bulletin of Japan Society of Laser Medicine, vol. 6, No. 3 (January 1986), pp. 71-76 & 347-350.

On the other hand, considerable attention has been paid to laser-chemical therapies including the method reported in 1987 by Dougherty et al of the United States. According to this method, 48 hours after an intravenous injection of a hematoporphyrin derivative (HpD), weak laser light such as argon laser or argon pigment laser is irradiated against a target area of the treatment. Whereupon oxygen of

the primary term which has a strong carcinostatic action is produced by HpD. Since then, there have been published various reports in this regard, including the one in the bulletin of Japan Society of Laser Medicine, vol. 6, No. 3 (January 1986), pp 113-116. In this connection, it has also been known in the art to use "pheophorbide a" as a photo-reactant. Further, recently, YAG laser has been put into use as a laser light source.

In the above mentioned medical treatment, it is important that the laser light is irradiated uniformly for the cancer tissues and, in case of the thermal therapy, it is particularly important that the cancer tissues are heated uniformly

However, it is difficult to irradiate the laser light uniformly and it is further difficult to irradiate against broad target area. Therefore, a following method should be carried out;

The laser light is irradiated many times against each small part of the target area separately so that the whole target area can be irradiated. Accordingly, it takes long time to perform the medical operation.

Under these circumstances, laser light irradiation apparatus having a plural number of laser light emitters or probes were studied. With apparatus of this type, each laser light emitted from each probe is irradiated simultaneously against the tissues. Such laser light irradiation apparatus was shown also by the inventor in his Japanese Patent Application No. 62-50723.

It is sure that the laser light can be irradiated against the tissues uniformly to some degree with these apparatus. However, uniformity is not enough. On the other hand, the plural number of laser light conduction passages and probes, further, a controller for the passages and the probes are necessary in these apparatus. Therefore, an increase in cost is produced.

It is therefore a main object of the present invention to provide inexpensive laser light irradiation apparatus by which laser light can be irradiated against living tissues uniformly.

Disclosure of the Invention

In order to solve the above mentioned problems, laser light irradiation apparatus of the present invention comprises a laser light penetrating member and at least one laser light transmitting member through which laser light goes so as to be fed into the penetrating member. Then, the laser light penetrating member contains laser light scattering particles and is fabricated from a laser light penetrating synthetic material.

In order to heat the tissues efficiently, a lead wire for detecting a temperature should be brought into contact with the treated tissues for temperature control.

Then, for heating the tissues, in laser light irradiation apparatus comprising the laser light penetrating member and at least one laser light transmitting member through which the laser light goes so as to be fed into the penetrating member, the laser light penetrating member contains laser light scattering particles and is fabricated from a laser light penetrating synthetic material, further the lead wire for detecting the temperature is preferably provided. This lead wire is inserted through the penetrating member so as to be projected from the external surface of the fore end portion of the penetrating member and whose inserting part is buried in the synthetic material of the penetrating member.

Now, comparing the prior art, the advantages of the present invention will be described.

Almost all of contact probes, which had been invented by the inventor, are fabricated from a ceramic material such as sapphire and the like. In this case, for the efficient laser light irradiation, there were only following methods; the surface of the probe was roughened or a laser light scattering surface layer was provided on the surface of the probe.

Since the probe fabricated from the ceramic material is excellent in heat resistance, the probe can be used effectively when the heat resistance is required. However, when the tissues are just heated in a thermal therapy and the like as described above, high power level of the laser light is not required. That is to say, the probe can be worked sufficiently with low power level of the laser light.

As the result of researches by the inventor, a synthetic material is found to be used for the probe as the penetrating member in the present invention. Then, by fabricating the synthetic material containing laser light scattering particles to be a predetermined shape, the laser light fed into the probe is scattered with the scattering particles in the probe. Therefore, the laser light is emitted in various directions from the surface of the probe. This produces a large area of laser light irradiation. Further, since the probe is fabricated from the synthetic material, the probe has also an advantage that it can be formed to be many types of suitable shapes according to the usage of the probe.

The lead wire for detecting the temperature in the tissues is necessary for controlling the temperature for a suitable medical treatment. Therefore, the probe can be formed from the synthetic material so that the lead wire for detecting the temperature such as the lead wire having a thermocouple at its fore end can be inserted through

the probe. In this case, the temperature is required to be detected at a position, which exists inside of the tissues and which is adjacent to the fore end of the probe being brought into contact with the surface of the tissues. Then, according to the present invention, detecting the temperature can be carried out precisely due to the suitable location of the lead wire. However, in the prior art, the temperature at the above mentioned position can not be detected by following reasons;

In the prior art, it has been known that the lead wire is provided separately with a probe or a balloon. Therefore, the thermocouple attached to the fore end of the lead wire is set to be inserted into the tissues at the side part of the probe. That is to say, the thermocouple can not be set the above mentioned position in the tissues due to the unsuitable location of the lead wire. Accordingly, it is impossible to detect the temperature at the above mentioned precise position. Alternatively, it has been known that the lead wire is passed around and attached from the side surface to the tip end of the probe and the fore end of the lead wire is attached to the tip end of the probe. By this method, the temperature at a point on the surface of the tissues adjacent to the fore end of the contacted probe can be detected. However, the detected temperature is that of the surface of the tissues or is not that of the inside of the tissues. As a result, by the conventional methods, it is impossible to detect the temperature at the precise position.

However, in the present invention, since the penetrating member or the probe is fabricated from the synthetic material, the probe can be formed so that the lead wire can be inserted through and buried in the synthetic material of the probe. The lead wire has the thermocouple at its fore end. Further, since the fore end of the lead wire is projected from the external surface of the fore end portion of the probe, when the probe is brought into contact with the tissues, the fore end of the lead wire can be inserted into the tissues together with the fore end of the probe. Accordingly, by apparatus of the present invention, the temperature at the precise position, which is adjacent to the fore end of the contacted probe and which exists inside of the tissues, can be detected. That is to say, the probe is excellent in temperature control for heating the tissues.

Brief Description of the Drawings

Fig. 1 is a longitudinal sectional view of an important part of laser light irradiation apparatus in a first embodiment related to the present invention; Fig. 2 is a side view taken on line II-II of Fig. 1; Fig. 3 is a perspective illustration showing an embodiment of local thermal therapy for cancer tissues

with laser light irradiation apparatus of the first embodiment and the temperature distribution diagram with this apparatus; Fig. 4 is a longitudinal sectional view of an important part of laser light irradiation apparatus in a second embodiment; Fig. 5 is a side view of apparatus of Fig. 4 from the left side; Fig. 6 is a longitudinal sectional view of laser light irradiation apparatus in a third embodiment; Fig. 7 is a longitudinal sectional view of an important part of laser light irradiation apparatus in a fourth embodiment; Fig. 8 is a longitudinal sectional view of an important part of laser light irradiation apparatus in a fifth embodiment; Fig. 9 is a longitudinal sectional view showing an embodiment of forming a guide in the tissues prior to inserting of laser light irradiation apparatus of Fig. 8.

The Best Mode to Carry Out the Invention

Now, the present invention is described more particularly with several kinds of embodiments.

Fig. 1 shows a first embodiment. An optical fiber 1, which serves as a laser light transmitting member, is surrounded by a sheath tube 2, which is fabricated from the resin of tetrafluorethylene and the like. The fore end portion of the optical fiber 1 is inserted through a nipple 3, which is fabricated from a synthetic material such as polyethylene and the like. A lead wire 4 for detecting a temperature has a thermocouple 4a at its fore end. Then, this lead wire 4 is provided along the optical fiber 1 and is also inserted through the nipple 3.

A flexible protective tube 5, which is fabricated from the resin of tetrafluorethylene and the like, is connected to the back end of the nipple 3. The back end of the optical fiber 1 is optically connected to a laser light generator (not shown). The lead wire 4 for detecting the temperature is connected to a temperature measuring unit (not shown). Then, according to the result of detecting the temperature, the power level of the laser light, which is fed into the optical fiber 1 from the laser light generator, should be controlled. This control is carried out by, for example, adjusting a timer switch, which is provided between the laser light generator and the back end of the optical fiber 1.

On the other hand, the fore end portion of the nipple 3 is connected to a holder 6 by means of a screw. The holder 6 at its fore end portion, holds a probe 7 as a laser light penetrating member.

The holder 6 comprises a body 6A, which is tapered toward its back end, and a sleeve-like connector 6B, which has a hollow shape and which is projected from the body 6A. The screw of the nipple 3 is adapted to mate with a connecting screw hole 6C of the holder 6 for connection. The optical fiber 1 and the lead wire 4 for detecting the temperature are inserted through the body 6A. The

probe 7 composes a substantial cylindrical part with a fore end circumference being rounded off and another cylindrical part at the back side of the substantial cylindrical part having a smaller radius by the thickness of the sleeve-like connector 6B. The smaller cylindrical part of the probe 7 is fitted in the sleeve-like connector 6B, further might be fixed integrally thereto by using an adhesive between the mating surfaces; a circumferential bottom face of the larger cylindrical part of the probe 7 and the top circumferential face of the sleeve-like connector 6B for high strength in fixing.

A laser light reflective layer 8 is formed on the mating surfaces of the probe 7 and the holder 6, in this embodiment, the circular front face of the body 6A and the internal side face of the sleeve-like connector 6B. Although the reflective layer 8 is preferably gold plated to give high heat resistance, it might be aluminum plated and the like in view of the material of the layer. For forming the layer, vapor-deposit as well as plating can be used.

Further, the fore end portion of the optical fiber 1 is inserted to be buried in the synthetic material of the probe 7 and the fore end of the core of the optical fiber 1 is contacted with the synthetic material of the probe 7 directly without any gap. The fore end portion of the lead wire 4 for detecting the temperature is inserted through the probe 7 so as to be projected from the external surface of the fore end portion of the probe 7 and has a sharpened tip end for inserting into the tissues easily.

The probe of the present invention contains laser light scattering particles and is fabricated from the laser light penetrating synthetic material. The material is synthetic resin such as silicone resin, acrylic resin (more preferably, methyl methacrylate resin), carbonate resin, polyamide resin, polyethylene resin, urethane resin, polyester resin and the like, more preferably, thermoplastic synthetic resin. For the scattering particles, the material, which has a larger refractive index for the laser light than that of the above mentioned synthetic material of the probe, is used, for example, a natural or artificial material such as diamond, sapphire, quartz material, single crystal zirconium oxide, laser light penetrating synthetic resin having heat resistance (it is needless to say that it is different from the above mentioned synthetic resin material of the probe), laser light reflective metal (such as gold, aluminum and the like), and these particles on whose surface the above mentioned laser light reflective metal is coated to be a compound material.

On the other hand, if desired, when the probe contains laser light absorbing particles such as carbon, graphite, iron oxide, manganese dioxide and the like together with the laser light scattering particles, the laser light is impinged on the absorb-

ing particles to generate heat energy while the laser light is scattered in the probe to be emitted from the probe.

The probe 7 of the present invention is made by moulding to be a desired shape from the synthetic material, which is in a molten state and into which the scattering particles are dispersed. In the present invention, the fore end portion of the optical fiber 1 is buried in the synthetic material of the probe 7 as shown in Fig. 1 and the middle part of the lead wire 4 for detecting the temperature is buried in the synthetic material of the probe 7 so as to be fixed integrally to the probe 7. Accordingly, for fabricating this apparatus, for example, the holder 6 is made easily by moulding from one mould to which the material is poured, while the optical fiber 1 and the lead wire 4 are projected from the body 6A of the holder 6.

Laser light irradiation apparatus of this type is used, for example, in a following manner. This apparatus is connected to an endoscope and inserted to a treated target area in a human body. At the same time, the laser light is generated from the laser light generator. Then, the laser light from the laser light generator is fed into the back end of the optical fiber 1 and is transmitted therein to be emitted from the fore end of the optical fiber 1. Continuously, the emitted laser light is fed into the probe 7 directly and is penetrated therein to be emitted from its external surface, while the laser light is refracted on the scattering particles many times in the probe 7. Therefore, as shown in Fig. 1, the laser light, after the many refraction, is emitted from the external surface of the probe 7 uniformly against the tissues. In this case, as shown in Fig. 1, the laser light reaching at the internal surface of the holder 6 is reflected on the reflection layer 8. Therefore, the metal holder 6 is prevented from being heated and from being damaged, further, the reflected laser light is brought to go forward.

Fig. 3 shows an embodiment where cancer tissues M are treated by a local thermal therapy with the probe 7 of the first embodiment. In this therapy, the external surface of the fore end of the probe 7 is brought into contact with the cancer tissues M. Then, the fore end portion of the lead wire 4 for detecting the temperature is projected from the external surface of the fore end portion of the probe 7 and is inserted into the tissues M. The temperature of the tissues M is detected with the thermocouple 4a for controlling the power level of the laser light fed into the optical fiber 1. In other words, the power level of the laser light emitted from the external surface of the probe 7 is controlled as described before. Then, the cancer tissues M are destroyed by keeping its temperature at about 42-44°C.

On the other hand, the laser light is irradiated

against also the lead wire 4 for detecting the temperature in the probe 7. Therefore, in order to prevent the lead wire 4 from being to be heated and from being to be damaged, the wire 4 is preferably coated with a laser light reflecting layer such as a gold plated layer and a titanium coating layer.

Figs. 4 and 5 show the second embodiment. The side face of a probe 10 is tapered toward the back end of the probe 10 to be a substantially truncated cone shape. Plural number of optical fibers 1 are provided in the probe 10, while the fore ends of the optical fibers 1 are buried in the synthetic material of the probe 10. In this embodiment, three optical fibers 1 are provided so that the fibers 1 are deflected toward the circumference of the fore end portion of the probe 10 to be apart each other from the back end of the probe 10 and, in a side view, the three fore ends of the fibers 1 are disposed circumferentially with the same angular space of 120°, as shown in Fig. 5. A holder 11 held by a medical operator directly has a fore end part, which is tapered towards the back end of the probe 10 so that the probe 10 can be fitted in the fore end part of the holder 11. A laser light reflecting layer 12 such as a gold plate layer is provided on the inner side surface of the tapered fore end part of the holder 11. A lead wire 13 is provided for detecting a temperature. Laser light irradiation apparatus of this second embodiment is mainly suitable for the laser light irradiation against the skin layer of a human body.

In the present invention, since the probe is fabricated from the synthetic resin material, comparing with a ceramic material, it is much easier to mould the material to be a desired shape. Therefore, as shown in the third embodiment of Fig. 6, the material can be moulded to be a probe 10A having an elaborated shape suitable for, for example, a treatment for uterin cancers formed adjacent to the cervical os of an uterin U.

In Fig 6 showing the third embodiment and Fig. 7 showing the fourth embodiment, each lead wire 4 for detecting the temperature is not projected from the external surface of the fore end portion of the probe 10A or a probe 7. That is to say, each fore end portion of each lead wire remains to be buried in the synthetic material of the probe 10A or the probe 7. In this case, if the relation of the temperature in the treated tissues and the temperature in the probe 10A or the probe 7 is known, the temperature of the tissues can be controlled by detecting the temperature in the probe 10A or in the probe 7, although the degree of accuracy in this control is more or less lowered.

Fig. 8 shows the fifth embodiment. In this embodiment, apparatus is used effectively in a treatment not for the surface of tissues but for inside of

the tissues.

At the fore end portion of an optical fiber 20, a clad 20B is removed so that a core 20A is exposed. The tip end of the core 20A is tapered. A laser light scattering layer is formed on almost all of the external surface of the core 20A. In this figure, this laser light scattering layer is directed by marking dots. For forming this scattering layer, first, ceramic powders such as silicon dioxide and the like are sprayed and heated to a temperature which is slightly lower than its melting point. Therefore, the original sprayed powders do not become to be homogeneous due to incomplete heating. Then, these incompletely heated ceramic powders are cooled. Accordingly, the laser light scattering layer can be formed on the core 20A, where the powders partly melt and partly remain. Due to this scattering layer, when the laser light is emitted from the external surface of the core 20A, the laser light impinges on each resulting ceramic powder with refraction to be scattered.

On the other hand, a probe 21 is provided so as to surround the core 20A covered with this scattering layer. The probe 21 is fabricated from a synthetic material containing scattering particles in the same manner as the first embodiment.

The external surface of a lead wire 22 for detecting a temperature is gold plated. Then, the fore end of the lead wire 22 fixed to the optical fiber 20 locates adjacent to the back end of the probe 21. The lead wire 22 together with the optical fiber 20 is surrounded by a flexible sheath 23, which is fabricated from synthetic resin such as polyethylene, urethane and the like, silicone rubber and so on. By moulding, the sheath 23 is fixed integrally to the lead wire 22, the optical fiber 20 and the probe 21.

In case of applying this apparatus of the fifth embodiment, as shown in Fig. 9, first, a so-called puncture needle 31 together with a guide tube 30 is inserted into the tissues M such as liver tissues. Next, only the puncture needle 31 is removed. Then, instead of the needle 31, the fore end portion of this laser light irradiation apparatus is inserted into the tissues M so as to go through the guide tube 30. Continuously, the laser light is fed into the optical fiber 20 to be emitted from the core 20A provided at the fore end portion of the optical fiber 20. Then, the laser light is scattered in the scattering layer covering the core 20A. Then, the scattered and emitted laser light is fed into the probe 21 and goes through it, while the laser light is scattered many times with the scattering particles in the probe 21. At last, the laser light is emitted from the external surface of the probe 21 uniformly. This apparatus is applied for a local thermal therapy for cancer tissues in a liver, encephalic malignant tumors and cancer tissues in a breast.

The scattering particles contained in the scattering layer are in principle the same as the above mentioned scattering particles in the probe. However, the particles, which can not make a film when they melt, are not suitable, thus, ceramic particles are generally used for the scattering particles.

Further, if desired, a surface layer might be formed on each surface of the above mentioned several kinds of probes or the above mentioned scattering surface layer covered on the core 20A to give a high scattering effect. This surface layer contains the light scattering particles, which have the larger refractive index than that of the material of the probe or the above mentioned synthetic material, such as sapphire, silicon dioxide, aluminum oxide and the like, the laser light absorbing particles, which can be included in the probe as described before, such as carbon and the like and a binder, which sticks the particles to each surface and forms a film on the surface as described hereinafter.

The laser light is scattered with the laser light scattering particles, further, when the laser light impinges on the laser light absorbing particles, the greater part of the energy of the laser light is converted to heat energy.

Therefore, as the vaporization of the tissues is accelerated, the tissues can be incised with a low energy of the laser light penetrated into the probe. Accordingly, when the tissues are incised, the probe can be moved rapidly. Further, since the required energy of the laser light penetrating into the probe is low, the medical operation can be carried in short time with a cheap and small scaled laser light generator.

On the other hand, referring to the surface layer, if a dispersion containing the laser light absorbing particles and the light scattering particles is coated on the surface of the probe, after a vaporization of a dispersion medium, the contact of the probe having the surface layer with the tissues or other substances causes a damage to the surface layer, because the both kinds of particles are attached to the surface of the probe only by physical adsorptive power.

Therefore, by the binder which sticks the laser light absorbing particles and the light scattering particles to the surface of the probe, an adhesion of the surface layer to the probe is enhanced. In this case, the binder is preferably made of light penetrating particles such as synthetic particles or ceramic particles such as quartz particles and the like. For forming the film, when the synthetic particles are used as the material of the binder, the particles should be melted, or when the ceramic particles having a higher melting point than that of the probe are used, the surface of the probe should be melted.

Further, by forming a rough surface on the surface of the probe or by forming the above mentioned surface layer on the rough surface, the laser light can be irradiated more effectively, because, the laser light is scattered on the rough surface when the laser light is emitted. If desired, the rough surface is formed on the core 20A, further the above mentioned scattering layer might be formed on the rough surface.

Although, in each embodiment described before, the fore end of the optical fiber is buried in the synthetic material of the probe, the fore end of the optical fiber might be located so as to be apart from the back end of the probe. However, an exception is the embodiment of Fig. 8, because the scattering layer in this embodiment is formed on the surface of the core and the probe is set to be provided so as to surround the core. Then, in case of providing a gap between the fore end of the optical fiber and the back end of the probe of the present invention other than the probe in the embodiment of Fig. 8, impurities such as dusts and the like are produced in the gap, further, the impurities are attached to the surfaces of the back end of the probe and the fore end of the optical fiber or fibers. Accordingly, since the laser light is impinged on the impurities, the surfaces of the back end of the probe are heated. That is to say, the power level of the laser light fed into the probe is lowered. Therefore, the fore end of the optical fiber is preferably buried in the synthetic material of the probe.

Industrial Utilization

As a result, by above mentioned laser light irradiation apparatus of the present invention, the penetrating member can be fabricated to be a desired shape easily, decrease in cost for fabricating apparatus is attained and the lead wire for detecting the temperature can be placed so as to be suitable for each medical treatment, further, the laser light can be irradiated against the living tissues uniformly.

Claims

1. Laser light irradiation apparatus comprising a penetrating member and at least one transmitting member through which laser light goes so as to be fed into said penetrating member, said apparatus being characterized by;
said penetrating member which contains laser light scattering particles and which is fabricated from a laser light penetrating synthetic material.
2. Laser light irradiation apparatus according to

claim 1, wherein said laser light transmitting member is an optical fiber and the fore end portion of a core of said optical fiber is buried in said synthetic material of said penetrating member.

3. Laser light irradiation apparatus according to claim 2, wherein a laser light scattering layer is formed on the surface of the buried part of said core.
4. Laser light irradiation apparatus according to claim 3, wherein said laser light scattering layer is fabricated from heat resistant ceramic particles partly melting and partly remaining to be in a particle-state.
5. Laser light irradiation apparatus according to claim 1, wherein said penetrating member is supported to be surrounded by a holder on its inner surface and a laser light reflecting layer covers at least a part of said inner surface.
6. Laser light irradiation apparatus according to claim 5, wherein said reflecting layer is a gold plated layer.
7. Laser light irradiation apparatus comprising a penetrating member, at least one transmitting member through which laser light goes so as to be fed into said penetrating member and a lead wire for detecting a temperature, said apparatus being characterized by;
said penetrating member which contains laser light scattering particles and which is fabricated from a laser light penetrating synthetic material; and
said lead wire which is inserted through said penetrating member so as to be projected from the external surface of the fore end portion of said penetrating member and inserting part of which is buried in said synthetic material of said penetrating member.
8. Laser light irradiation apparatus according to claim 7, wherein at least said inserting part and the projecting part of said lead wire are coated by a laser light reflecting material.
9. Laser light irradiation apparatus according to claim 1 or 7, wherein a surface layer is formed on the surface of said laser light penetrating member and said surface layer contains laser light absorbing particles, light scattering particles having a larger refractive index than that of said penetrating member and a laser light penetrating material as a binder.

10. Laser right irradiation apparatus according to any claim of claims 1, 7 and 9, wherein a rough surface is formed on the surface of said laser light penetrating member.

V. ☐ OBSERVATIONS WHERE CERTAIN CLAIMS WERE FOUND UNSEARCHABLE *

This international search report has not been established in respect of certain claims under Article 17(2) (a) for the following reasons:

1. ☐ Claim numbers ... , because they relate to subject matter not required to be searched by this Authority, namely:
2. ☐ Claim numbers ... , because they relate to parts of the international application that do not comply with the prescribed requirements to such an extent that no meaningful international search can be carried out, specifically:
3. ☐ Claim numbers ... , because they are dependent claims and are not drafted in accordance with the second and third sentences of PCT Rule 6.4(a).

VI. ☐ OBSERVATIONS WHERE UNITY OF INVENTION IS LACKING *

This International Searching Authority found multiple inventions in this international application as follows:

1. ☐ As all required additional search fees were timely paid by the applicant, this international search report covers all searchable claims of the international application.
2. ☐ As only some of the required additional search fees were timely paid by the applicant, this international search report covers only those claims of the international application for which fees were paid, specifically claims:
3. ☐ No required additional search fees were timely paid by the applicant. Consequently, this international search report is restricted to the invention first mentioned in the claims; it is covered by claim numbers:
4. ☐ As all searchable claims could be searched without effort justifying an additional fee, the International Searching Authority did not invite payment of any additional fee.

Remark on Protest

- ☐ The additional search fees were accompanied by applicant's protest.
☐ No protest accompanied the payment of additional search fees.
